ABSTRACT

Students whose reading achievement was average, below average, and above average were compared on measures of educational and occupational background, family characteristics, and elementary school performance prior to grade 6. Results were analyzed separately by sex, race (Negro and Caucasian), both sexes and races combined, and upper and lower socioeconomic and mental ability levels. Findings which achieved statistical significance included: (1) differences among achievement groups in parents' marital status were significant only in the Caucasian male sample; (2) parents' education and occupation had a greater relationship to reading achievement for girls than for boys and particularly for girls with higher IQ scores; (3) among those retained in a grade, differences among achievement groups were significant only in the Negro female sample; (4) the difference between achievement groups on socioeconomic level of father was significant for Negro females; and (5) the decrease in performance from grade 3 to grade 6 was significantly greater for underachievers than for average and overachievers. Supplemental Data on High and Low IQ and SES Groups in Four Race-by-Sex Samples included. See Part One [ED 034 660] and Part Two [CS000078]. (Author/RD)

Summary

Underachievers, average achievers, and overachievers in reading, classified according to the discrepancy between 6th grade reading score and reading level predicted from a 6th grade test of mental ability, were compared on measures of educational and occupational background, family characteristics, and elementary school performance prior to the 6th grade. Data were analyzed separately for sex and race (Negro and white) samples and the four samples combined. In addition, relationships in the combined samples were compared across upper and lower levels of socio-economic status (SES) and upper and lower levels of mental ability (6th grade IQ scores above and below 100).

In the combined samples, parents of underachievers had a significantly lower mean educational level, occupational level, and SES level (a weighted combination of father's educational and occupational level) than parents of average or overachievers. The relationship of these variables to reading achievement, however, was small, and differences were not significant in all samples and stratifications.

The differences among achievement groups in educational and occupational background were most significant in the upper SES levels, indicating that families at successively higher educational levels (college graduates and above) produce the fewest underachievers.

There was also an interaction of educational and occupational background, sex, IQ, and reading achievement. Parents' education and

occupation had a greater relationship to reading achievement (or influence on, if causality is assumed) for girls than for boys, and particularly for girls with higher IQ scores.

Differences among the achievement groups on other measures of family characteristics were either not significant or showed negligible relationships to reading achievement. Underachievers had a higher mean number of siblings than average achievers; however, this difference was only significant among white males in the lower IQ range. Difference among achievement groups in marital status of parents was also found to be significant only in the white male sample. White male underachievers in lower SES and lower IQ ranges came from broken homes more often than did average and overachievers. Among white males in the upper SES and upper IQ ranges, differences were not significant.

In the Negro male and Negro female samples, there were very few significant differences on SES and family characteristic measures. In the Negro male sample, there were no significant differences on any of these measures. The difference between achievement groups on educational and occupational levels of father for Negro females approached significance; the difference on SES level was significant. In part, failure to find significant differences in the Negro samples could be attributed to the restricted variance on some measures. In the Negro samples, number of siblings was not linearly related to reading achievement. Among both Negro males and Negro

females, the lowest percentage of underachievers was found in small families (0 to 2 siblings) and large families (6 or more siblings). In contrast to the pattern in the white male and white female samples, the highest percentage of average and overachievers in the Negro samples came from large families.

Measures of earlier elementary school performance consisted of 3rd grade reading and IQ test scores and whether or not subjects had been retained in grade during elementary school. These data were available only for those subjects in the 6th grade cohort who were in the school system in earlier grades.

Although underachievers were retained more often in elementary school grades than average or overachievers, the difference among achievement groups was only significant in the Negro female sample.

Comparison of achievement groups on 3rd and 6th grade reading performance produced five findings: (1) underachievers were reading at a significantly lower level than average or overachievers in the 3rd grade, (2) there was a decrease from the 3rd to the 6th grade in reading relative to grade placement for underachievers and average achievers, (3) overachievers, on the other hand, maintained the same superior level of performance from grades 3 to 6, (4) the decrease in performance from grades 3 to 6 was significantly greater for underachievers than for average and overachievers, (5) the degree to which scores changed from grades 3 to 6 was related to reading level (grade placement) in the 3rd grade. The findings indicate that normative level of achievement and relative

level of achievement tap different aspects of reading ability and have different implications for reading achievement over time. Both should be considered in the diagnosis of reading difficulties and planning of reading programs.

Relationships of Family Background and Third Grade Performance to Sixth Grade Reading Achievement

Dee Norman Lloyd

Research findings have generally shown that measures of socio-economic level are positively related to academic performance (Lavin, D. E., 1965). In studies where level of intelligence has been controlled, socio-economic variables have still differentiated underachievers from average or overachievers (Vane, J. R., 1966). From the review of the literature, however, most studies have used a matching procedure to equate groups on IQ level or socio-economic status, and the focus of investigation has been largely on under-achievers in the upper range of mental ability. The procedure in the present study provided an assessment of reading achievement over the entire range of mental ability. Three achievement groups (underachievers, average achievers, and overachievers) were formed on the basis of discrepancy between obtained reading level and reading level predicted by a test of general mental ability. These groups were compared on measures of parents' education and occupation, family characteristics, and measures of elementary school performance. Since the achievement groups did not differ significantly in their mean IQ scores in the 6th grade, the relationships of these variables to reading achievement would indicate relationships over and above those accounted for by mental ability. More specific relationships across achievement groups were also

investigated by stratifying the sample into high and low IQ and SES levels, and comparisons were also made within the four race-by-sex samples in the study population.

Method

Subjects

Subjects were 3651 6th grade students who had both the CTMM IQ score and CAT Reading score that were used to define achievement groups (see Part I). Analyses were performed for this sample (combined samples) and for the four separate race and sex samples. The individual race and sex samples consisted of 1624 white males (WM), 1600 white females (WF), 231 Negro males (NM), and 196 Negro females (NF). Analyses were also performed with the combined samples stratified (1) into high and low SES levels and (2) into high and low IQ score levels. High and low SES groups consisted of 1487 and 1971 subjects. High and low IQ groups consisted of 2157 and 1494 subjects, respectively.

Variables

The independent variables in this analysis were measures of occupational level, educational level, and marital status of parents, number of siblings, elementary school progression, and performance on standardized tests in the 3rd grade. All measures of parent and family characteristics reflected the status that was recorded in school records when the subject was in the 6th grade.

Educational levels of the subject's father and mother were coded into three categories: elementary, high school, and beyond high school. These three levels were coded 6, 4, and 1, respectively, in order to compute the Hollingshead Two-Factor Index of Social Position (Hollingshead, 1957). The occupational level of the father consisted of a seven-category scale adapted from the occupational scale of the Index of Social Position (Hollingshead and Redlich, 1958). A summary of the seven occupational levels in this scale is as follows:

Level 1: Higher executives, proprietors, and professionals
Level 2: Lesser executives, proprietors, and professionals
Level 3: Administrative, small business owners, minor and semi-professionals
Level 4: Clerical, sales, and technicians
Level 5: Skilled trades
Level 6: Semi-skilled trades
Level 7: Unskilled workers

The Hollingshead Two-Factor Index (SES level) consisted of a weighted composite of the occupational and educational levels (occupation weighted 7 and education weighted 4). The father's educational and occupational level were used to compute the SES level if that information was available. If information for the father was not available,or if the father was not living with the family, the index was computed from information available for the mother.[1]

---

[1] The scaling of educational, occupational, and SES levels had a reverse correspondence to amount of education, etc. In interpreting results involving these measures, lower mean scores indicate higher levels.

Measures of family characteristics were the number of siblings of the subject and the marital status of parents. The former variable was coded directly, the latter consisted of two categories indicating (1) that the subject's natural parents were alive and married, and (2) that the natural parents were separated, divorced, deceased, or remarried.

Measures of elementary school performance prior to the 6th grade were the 3rd grade California Achievement Test Total Reading score (3rd grade CAT Reading score), the IQ score from the 3rd grade California Test of Mental Maturity (3rd grade CTMM IQ score), and whether or not a subject had been retained in grade during elementary school (school progression).[2] Third grade test scores were available for only those subjects in the 6th grade cohort who were in the school system from the 3rd to 6th grades. This was approximately 60% of the original 6th grade sample.

Procedures

A discrepancy score that represented the difference between expected reading level (predicted from the 6th grade CTMM IQ score) and obtained reading level (6th grade CAT Total Reading score) was used to define three achievement groups: underachievers, average

---

[2] The 3rd grade CAT reading test was administered between the 4th and 6th month of the school year (1952-53 for normal progression subjects). Test was the 1950 edition, primary form AA. The IQ score was from the 1950 edition, short form, primary level California Test of Mental Maturity.

achievers, and overachievers. Achievement groups were formed on the basis of the standard error of estimate (S.E.E.) for predicting the 6th grade CAT Reading score from the 6th grade CTMM IQ score. Underachievers had discrepancy scores below 1 S.E.E.; average achievers had discrepancy scores between plus and minus 1 S.E.E.; and overachievers had discrepancy scores above 1 S.E.E. (see Part I).

In the race and sex samples, the expected reading scores were derived from the regression of the IQ score and the reading score for each sample (see Part II). That is, the definition of under-, average, and overachievement was controlled for differences in the relationship of IQ and reading level that might exist across sex and race.[3] Standard errors of estimate in the four race and sex samples, however, were similar enough to permit the use of one cut-off score for defining achievement groups in all samples (discrepancy score of plus and minus .85). Only in the Negro female sample, where the standard error of estimate was .768, did this affect the classification of subjects.[4]

---

[3]The Pearson product-moment correlations between the 6th grade CTMM IQ score and the 6th grade CAT Reading score were of different magnitude, particularly across race. Coefficients in the four samples were .82 (WM), .78 (WF), .61 (NM), and .74 (NF).

[4]Discrepancy scores were rounded to one-tenth of a grade-equivalent score so that subjects with a score of -.9 or below were classified as underachievers, and subjects with scores of +.9 or above were classified as overachievers. Four Negro females who had scores of -.8 and would have been classified as underachievers by the S.E.E. in that sample were classified as average achievers for this analysis. One Negro female had a score of +.8 and was classified as an average achiever rather than as an overachiever.

In order to investigate the relationship of reading achievement to other measures at different levels of mental ability, two groups were formed on the basis of scores on the 6th grade CTMM. The high IQ level consisted of subjects with 6th grade CTMM IQ scores of 100 and above; the low IQ level consisted of subjects with scores below 100. For comparison of reading achievement in groups with d'fferent socio-economic status background, subjects were classifie. into high and low groups on the Two-Factor Index of Social Position. High SES level consisted of subjects from levels 1, 2, and 3; low SES level consisted of subjects from levels 4 and 5.[5]

Statistical analyses consisted of analysis of variance tests across the three achievement groups, with the omega^2 statistic as an index of association, or chi square comparisons where appropriate.

---

[5]The comparisons of high and low SES and IQ levels are reported for the combined samples, i.e., under-, average, and overachievers in all four race and sex samples. Since the majority of Negro subjects had IQ scores below 100 and were concentrated in the lower SES levels, most Negro subjects were included in the lower levels of these stratifications. Comparisons of high and low IQ and SES groups within the separate race-by-sex samples were made to determine possible interaction effects and to pinpoint specific subgroups contributing to significant differences across achievement groups. For these analyses, high and low IQ and SES were defined in the Negro samples to achieve a more balanced comparison. High and low IQ levels were defined as an IQ score of 86 and above and 85 and below, respectively. High SES was defined as levels 1 through 4 of the two-factor index, low SES as level 5. Results from these data will be referred to only when they add to or contradict results obtained from stratifications in the combined samples. Data for the IQ and SES groups in the separate race-by-sex samples are contained in a supplement to this study, copies of which are available from the author.

Results

General Distributions on Variables

Distribution of the four race-by-sex samples on the experimental variables were compared to provide a basis for interpreting differences across samples that might be found when the relationships to reading achievement were assessed.

In Table 1, means and standard deviations of the four race-by-sex samples and the combined samples on family measures are presented. Mean differences across race samples were significant on all variables. The Negro samples had lower mean educational level of father, educational level of mother, occupational level of father, and SES level than the white samples, and Negro samples had a higher mean number of siblings than the white samples. Differences on these variables between white males and white females and between Negro males and Negro females were not significant.

Percentages in categories of marital status of parents are given in Table 2. The chi-square tests between race samples were significant ($p < .02$ and $p < .01$), with the Negro samples showing a higher percentage than the white samples of parents who were separated, divorced, or deceased. Differences between sexes within race were not significant, although there was a higher percentage of separated, divorced, or deceased parents among white females (12%) than among white males (9.9%).

Table 2

Marital Status of Parents of Race-by-Sex and Combined Samples

	Natural Parents Married		Natural Parents Separated, Divorced, Deceased, or Remarried	
	N	%	N	%
White Males (N=1565)	1410	90.10	155	9.90
White Females (N=1545)	1359	87.96	186	12.04
Negro Males (N=226)	186	82.30	40	17.70
Negro Females (N=191)	157	82.20	34	17.80
Combined Samples (N=3527)	3112	88.23	415	11.77

Table 3

Elementary School Progression for Race-by-Sex and Combined Samples

	Regular Progression		Retained-in-Grade	
	N	%	N	%
White Males (N=1511)	1361	90.07	150	9.93
White Females (N=1502)	1428	95.07	74	4.93
Negro Males (N=224)	140	62.50	84	37.50
Negro Females (N=191)	136	71.20	55	28.80
Combined Samples (N=3428)	3065	89.41	363	10.59

In Table 3, the elementary school progression of the samples is presented. Comparisons between race samples revealed that the Negro students were retained-in-grade significantly more often than white students ($p < .001$). White males were retained significantly more than white females ($p < .001$). Negro males were retained more than Negro females; however, this difference was not statistically significant.

The mean performance of the samples on the 3rd grade standardized tests are given in Table 4. On the 3rd CTMM IQ score, there were significant differences between race samples and no significant differences between sex samples within race. The difference in mean 3rd CAT Reading score was also significant across race. Within both races, female samples had a higher mean reading level than the male samples; this difference was significant between white males and white females ($p < .001$), but not significant between Negro males and Negro females.

As anticipated from previous analyses, the Negro and white samples differed significantly on all variables. These differences indicated that the Negro samples largely came from lower socioeconomic background and had a lower test performance level than the white samples. Therefore, in the analysis of reading achievement, the focus of comparison across race did not concern level of performance, but was directed at determining whether the relationship of reading achievement to other characteristics was the same or different in the two race groups.

Table 4

Mean Performance on 3rd Grade Standardized Tests for Race, Sex, and Combined Samples

Variables		White Males	White Females	Negro Males	Negro Females	Combined Samples
3rd CTMM IQ score	N	1075	1023	143	125	2366
	M	108.63	108.50	93.70	92.40	106.81
	SD	16.25	15.54	15.37	16.25	16.63
3rd CAT total reading score	N	1029	965	138	109	2241
	M	3.75	4.09	3.15	3.44	3.85
	SD	.95	.84	.83	.85	.93

With two exceptions, males and females did not differ significantly on characteristics under investigation, and the exceptions were in agreement with established sex differences (higher reading level for females, higher retention rate for males). The comparability of the sex samples makes it possible to look for replication of relationships to reading achievement in two samples and to evaluate sex-related differences by their replication across race.

Relationship of Educational Level of Parents to Reading Achievement

The comparisons across the three achievement groups on educational level of father are presented in Table 5. In the combined samples the difference in mean educational level was statistically significant ($p < .001$), with underachievers having fathers with lower educational levels than fathers of average or overachievers. The omega^2 statistic indicated that educational level of father accounted for 0.9% of the variance among achievement groups.

With the stratification of the sample into high and low SES level, a significant difference in educational level of the father was not expected because this measure was a component of the SES classification. In the high SES group, however, the difference among achievement groups remained significant ($p < .05$). Underachievers from high SES levels had fathers with lower educational level than did high SES average achievers and overachievers. This significant difference most likely resulted from the limited number of categories on this variable. The upper category included any

[a] $p < .05$

[b] $p < .01$

[c] $p < .001$

educational training beyond high school, ranging from additional vocational or business training to graduate and advanced professional degrees. The significant difference among high SES achievement groups suggested (1) that a more differentiating scale of educational level would reveal a greater association to reading achievement, and (2) that in the highest educational levels the fewest underachievers would be found.

When the combined samples were stratified into high and low IQ levels, the relationship of educational level of father to under-, average, and overachievement in reading was found to be significant at both levels. The direction of the difference among groups was the same as that for the total sample, and the percentage of variance accounted for was approximately the same.

In the race-by-sex samples, educational level of father was significantly related to reading achievement in the white samples. The omega^2 statistic and the significance levels also indicated that the relationship was greater for white females than for white males. Although differences were not statistically significant in the two Negro samples, the trend was in the same direction as in the white samples, with underachievers showing the lowest mean level. The association was also relatively greater for Negro females than for Negro males.

The educational level of father in high and low IQ levels within separate race-by-sex samples indicated that there was also an interaction effect of sex and IQ level in the relationship

of educational level and reading achievement. In the high IQ level, achievement groups differed significantly in educational level of father in the white female sample ($p < .001$; $omega^2 = 2.26$) and the Negro female sample ($p < .001$; $omega^2 = 8.93$), but these were not significantly different in the white male and Negro male samples. In the low IQ level, the relationship of educational level of father was significant for white males ($p < .05$; $omega^2 = 0.72$) and for white females ($p < .001$; $omega^2 = 1.87$) but not for Negro males or Negro females. Thus, the relationship of educational level to reading achievement among white males appeared to hold predominantly in the low IQ range. The relationship among white females, although significant in both high and low IQ levels, was greater in the high IQ range. The relationship of father's educational level in the Negro female sample, which was not sufficient to produce a significant difference across achievement groups among all Negro females, did show a significant relationship among high IQ Negro females, thereby increasing the evidence for a stronger association of educational level of father to reading achievement among high IQ females.[6]

The mean educational levels of mother for the three achievement groups in the various groupings are presented in Table 6. The relationship of educational level of mother to reading

---

[6]High IQ level for Negro females was defined as a 6th CTMM IQ score of 86 or above; high IQ level for white females was defined as an IQ score of 100 or above, see Procedures section.

achievement showed the same pattern as educational level of father in all samples and stratifications, but the relationship was not as strong. In the combined groups, educational level of mother accounted for 0.3% of the variance across the achievement groups compared to 0.9% for educational level of father. The difference between the groups did not reach significance in the white male sample, and the significant level of the difference in the white female sample was lower. Comparing other figures in Table 6 with those in Table 5, it can be seen that the relationship of educational level of mother in the high and low SES levels was approximately the same as that for educational level of father. In the high and low IQ levels,the difference among achievement groups in educational level of mother did not reach significance in the low IQ level, and the difference was at a lower significance level in the high IQ level than that for educational level of father. Examination of the differences in educational level of mother across stratifications in the individual samples showed the same relationships that were found for educational level of father. A significantly lower mean of underachievers in the high SES level resulted solely from the significant difference in the white female sample. In the high IQ level, underachievers showed a significantly lower educational level of mother only in the female samples ($p < .05$ for white females; $p < .001$ for Negro females).

The results indicated that the relationship of educational level of parents to achievement in reading was primarily characteristic of females. This finding was replicated on two measures, one for father and one for mother, and across race groups. Further, the relationship resulted primarily from differences in the high IQ level. If IQ and educational level of parents are considered as determiners of reading achievement, the results showed that females with a high IQ profit more from the higher educational background in the home than do males. For males, the results suggest the reverse, for it was only in the low IQ range that educational level of father was significantly related to reading achievement (white male sample, $p < .05$).

Relationship of Occupational Level of Father to Reading Achievement

In the combined samples, occupational level of father was significantly different across the three achievement groups, with underachievers coming from the lowest mean occupational level (Table 7). The variance accounted for among groups by occupational level (0.8%) was similar to that accounted for by educational level of father (0.9%).

At high and low SES levels, the occupational level of father was not significantly different across achievement groups (this variable was a component in the SES classification). There was a significant difference in both high and low IQ levels, with a higher significance level and slightly greater percentage of variance accounted for in the upper IQ range than in the lower IQ

[a] $p < .05$

[b] $p < .01$

[c] $p < .001$

range. As in the relationships of educational level to reading achievement, significant relationships resulted from differences in the two white samples, and primarily in the white female sample. For white females, the occupational level of father accounted for 1.9% of the variance across achievement groups compared to 0.4% in the white male sample. Although the association was not significant in either of the Negro samples, there was a stronger relationship of occupational level to achievement among Negro females than among Negro males.

In the high and low IQ level stratification in the individual samples, the same interaction occurred between IQ level and sex that was found with the measures of educational level. There was not a significant difference among achievement groups in mean occupational level of father in the male samples in the high IQ range, whereas the relationship was significant in both female samples ($p < .001$; $omega^2 = 2.27\%$, for white females and $p < .01$; $omega^2 = 5.59\%$ for Negro females). In the low IQ range, differences were only significant in the white male ($p < .05$; $omega^2 = 0.68\%$) and white female ($p < .05$; $omega^2 = 1.08\%$) samples.

Relationship of SES Level to Reading Achievement

Differences across achievement groups in SES level paralleled those found for educational and occupational level of father, the two components of this measure. Underachievers had a lower mean SES level than average and overachievers in all comparisons shown

in Table 8, with the exception of the low IQ level and Negro male sample. As with educational level of father, the difference among achievement groups remained significant in the high SES stratification, and differences were significant in both high and low IQ stratifications. As with educational and occupational levels of father, significant relationships of SES level to reading achievement resulted primarily from the differences in the female samples. The significant difference of achievement groups in the high SES level resulted solely from the difference in the white female sample ($p < .05$; $omega^2 = 0.88\%$). In the high IQ range, differences were not significant among achievement groups in the two male samples, but were highly significant in the two female samples ($p < .001$).

A methodological question relevant to the prediction and description of reading achievement concerns the usefulness of the weighted SES score as opposed to the prediction produced by the separate components of this composite score. With one exception, the significance level and percentage of variance figures in Table 8 (SES level) did not differ appreciably from the figures in Table 5 (Educational Level of Father) and Table 7 (Occupational Level of Father). This suggested that either the educational or occupational measure could be used to account for the differences across reading achievement groups in place of the more complexly-derived SES measure. The one exception where prediction was better with the

SES measure than with either of the educational or occupational components was in the Negro female sample. In this sample, average and overachievers differed in mean educational and occupational level of father, but these differences were not statistically significant. Combining these two measures to obtain an SES level score increased the differences among the achievement groups to a statistically significant level ($p < .05$).

Relationship of Other Family Characteristics to Reading Achievement

Underachievers, average achievers, and overachievers were compared on number of siblings and marital status of parents.

The mean number of siblings for achievement groups is presented in Table 9. There was a significant difference across achievement groups in the combined samples, with underachievers having a higher number of siblings than average or overachievers. A similar relationship, however, was not consistently found in the stratifications of the combined samples and the individual samples. Although there were trends across achievement groups, significant differences were only found in the low IQ level and the white male sample. Where significant differences and trends occurred, means of the achievement groups indicated that the relationship of number of siblings to reading achievement resulted primarily from the fewer siblings of overachievers rather than the greater number for underachievers. The indication that the relationship of number of siblings to reading achievement was primarily

[a] $p < .05$

characteristic of low-IQ-level white males was supported by the relationships within the white male sample. The difference in number of siblings was significant ($p < .05$; omega^2 = 0.92%) across achievement groups in the low IQ level, but it was not significant across high-IQ white male achievement groups.

The trend of means across achievement groups in the Negro male sample was opposite from that in the white samples. Negro male underachievers had the lowest mean number of siblings, and overachievers had the highest mean number of siblings. In the Negro female sample a trend was not clear; both underachievers and overachievers had fewer siblings than average achievers.

A closer examination of family size in the Negro samples indicated that fewer underachievers came from small and large families, in contrast to the white samples where the incidence of underachievement consistently increased with increase in family size. In the Negro samples, 22% of underachievers had two or less siblings compared to 24% of average achievers and 28% of overachievers. Considering large families, 18% of underachievers had six or more siblings compared to 42% of average achievers and 44% of overachievers. In contrast, 26% of the white male underachievers had six or more siblings, compared to 5% of average achievers and only 2% of overachievers. Although the distribution of number of siblings across achievement groups was not significant in the Negro samples when tested by chi square,

there was definitely a different relationship to reading achievement from that found in the white samples. Large family size was more often associated with average and overachievement than with underachievement.

The marital status of the subjects' natural parents was coded into the following categories: married, separated, divorced, deceased, or remarried. The percentages in each of these categories were tabulated for the achievement groups. In addition, a dichotomous variable was formed to compare all of the categories that reflected a change in marital status prior to the 6th grade with the "married" category. The percentages of subjects in the three achievement groups whose parents were recorded as being separated, divorced, deceased, or remarried when the subject was in the 6th grade are presented in Table 10. The only significant difference in marital status occurred in the white male sample ($p < .05$; $C = .07$). Among white males, a higher percentage of underachievers than average or overachievers had parents whose marriage had been disrupted. Examination of the relationship of marital status to achievement within the white male sample revealed that the significant difference largely resulted from differences in the low SES level ($p < .01$; $C = .11$). White male underachievers had a higher percentage than average and overachievers in each of the change categories (separated, divorced, deceased, or remarried); so, there was no indication that one category was more highly related to underachievement than the others.

Table 10

Note.-Figures represent the number and percentage of subjects in each group whose parents had been separated, divorced, deceased, or remarried at the time the subject was in the 6th grade. The break points for defining high and low IQ levels were an IQ score of 100 in the white samples and an IQ score of 85 in the Negro samples.

[a] $p < .05$

Elementary School Progression

The percentages of subjects in the achievement groups who were retained in grade between grades 1 and 6 are presented in Table 11. Underachievers were retained slightly more than average achievers in all samples and in the combined samples. The difference among the three achievement groups, however, was only significant in the Negro female sample ($p < .05$). Further, the difference in the percentage of Negro females retained was only significant in the low SES range ($p < .02$, $C = .22$) and low IQ range (IQ below 85, $p < .05$, $C = .28$).

With the exception of the findings in the Negro female sample, retention in elementary school did not appear to be related to underachievement in reading when general level of mental ability was controlled. Comparison of the figures in all achievement groups across high and low IQ and SES ranges, however, showed that elementary school retention was highly related to IQ score and SES level. The over-all retention rate for students in the white samples with IQ scores above 100 was approximately 2% compared to the retention rate of 17% for students with IQ scores below 100. This strong relationship of retention to ability or general achievement suggests that decisions to retain a student were primarily based on normative level of performance and not on discrepancy between performance and ability, i.e., achievement

Table 11

Note.-The breakpoint for defining high and low IQ ranges in the white samples was an IQ score of 100; the breakpoint in the Negro samples was an IQ score of 85.

[a] $p < .05$

as defined in this study.[7]

Relationship of 3rd Grade Test Performance to Reading Achievement

For the subjects who were in the 3rd grade, two test scores were available, the 3rd grade CTMM IQ score and the 3rd grade CAT Reading score.

Achievement groups differed significantly in 3rd grade CTMM IQ in the high and low SES levels, high IQ level, and in the white male and white female samples, with underachievers having the lowest mean IQ (Table 12). Underachievers also had a lower mean IQ score than average achievers; in the low IQ level and in the Negro male and Negro female samples, however, differences were not statistically significant. The largest differences occurred among white males and white females in the high IQ level. Significant differences in mean 3rd grade IQ of the achievement groups supported other evidence (Part I) of some misclassification of subjects due to the reliability of the 6th grade test scores. Where significant differences in 3rd grade CTMM IQ score occurred, however, the percentage of variance accounted for across achievement groups was

---

[7] In some of the comparisons presented in Table 11, the percentage of retention among overachievers was higher than that for average achievers. The method of defining achievement groups may have contributed to this finding. Expected reading level was based on the IQ score, which included chronological age. As previously discussed (see Discussion section of Part I), students who have been retained may have lower IQ scores in grades following the retention by virtue of increased age alone. This, in turn, would increase the probability of retained students being classified as overachievers.

[a] $p < .05$

[b] $p < .01$

small, exceeding 1% only in the white female sample and in the high IQ level.

Comparison of the 6th grade underachievers, average achievers, and overachievers on 3rd grade reading performance was directed at determining whether underachievers in the 6th grade revealed a history of underachievement back to the primary grades, or whether development of reading skills in the 4th and 5th grades was more critical to achievement status in the 6th grade.

Comparisons of the three achievement groups on the 3rd grade CAT Reading score are presented in Table 13. With the exception of the Negro male sample, the mean 3rd grade reading level of underachievers was significantly below that of average and overachievers in all samples and stratifications ($p < .001$). In the Negro male sample, the trend of means was in the same direction as in other samples, and the difference across achievement groups approached significance. The percentage of variance accounted for across the achievement groups by the 3rd grade CAT Reading score was much greater than that accounted for by the 3rd CTMM IQ score, indicating that differences in IQ could not account for all differences in reading level.

The lower 3rd grade reading level of the 6th grade underachievers supported the hypothesis that many underachievers had a history of underachievement in relation to the level expected from their mental ability score at least as far back as the 3rd grade.

[a] $p < .001$

There were other characteristics in the reading performance of the study sample that need to be considered in order to evaluate the performance of the achievement groups from grades 3 to 6. First, it was noted that the mean reading level of subjects with 3rd grade reading scores was .4 grade equivalents above normative placement in the 3rd grade (Table 4); whereas, the mean 6th grade CAT Reading score for all subjects in the study was .3 grade equivalents below the 6th grade norm. The higher 3rd grade reading level of subjects with 3rd grade scores can also be seen in Table 13, where the mean reading score of underachievers (combined samples) was at grade placement (3.4). By comparing the 6th grade performance of the subgroup of subjects with 3rd grade scores with that of the complete sample, it was possible to determine whether the smaller group was representative of the complete sample or whether it was a select, higher-performing group. Data for these comparisons is presented in Table 14. The 3rd grade samples had only slightly higher 6th grade reading and IQ scores than the complete 6th grade sample, and none of the differences on the 6th CAT Reading score was statistically significant. Thus, the decrease in reading level relative to the norm grade placement did not appear to result from selection of subjects. Differences in tests could also be ruled out as a cause of the decrease, since they were from the same publisher, and the norms were as comparable as can be obtained across grades. This would

suggest that the cause of the general drop in reading level from grades 3 to 6 was related to characteristics of the reading curriculum in the schools in the intervening grades between tests.[8]

The findings developed this far would indicate (1) that underachievers were performing at a significantly lower level than average and overachievers in the 3rd grade, (2) that the subjects with 3rd grade scores were representative of the complete study sample in their performance in the 6th grade, and (3) that there was a general drop in reading level relative to grade placement from grades 3 to 6. In light of these findings, there were interesting differences in the performance of underachievers, average achievers, and overachievers from grades 3 to 6.

In Figure 1, the mean score of each achievement group in the combined sample is expressed in terms of the deviation in grade-equivalent units from the norm grade-placement for the 3rd and 6th grade testings. In Figure 2, comparable data for the race-by-sex samples is depicted. In the combined samples, overachievers, whose mean reading level in the 3rd grade was .9 grade equivalents above norm placement, were also reading .9 grade equivalents above grade placement in the 6th grade. In contrast, the mean performance of

---

[8] Cross-sectional data from the County testing program in the years that the study subjects were in grades 6 to 8 show the same effect as the cohort data above. That is, the 3rd grade classes during these three years had a mean reading level that was at or above norm placement; whereas, 5th and 6th grade classes had mean reading scores that were .2 or .3 grade equivalents below the norm.

FIGURE 1

MEAN 3rd AND 6th GRADE READING LEVELS OF UNDER-, AVERAGE, AND OVERACHIEVERS CORRECTED FOR GRADE LEVEL (ALL SUBJECTS WITH BOTH SCORES, N=2241)

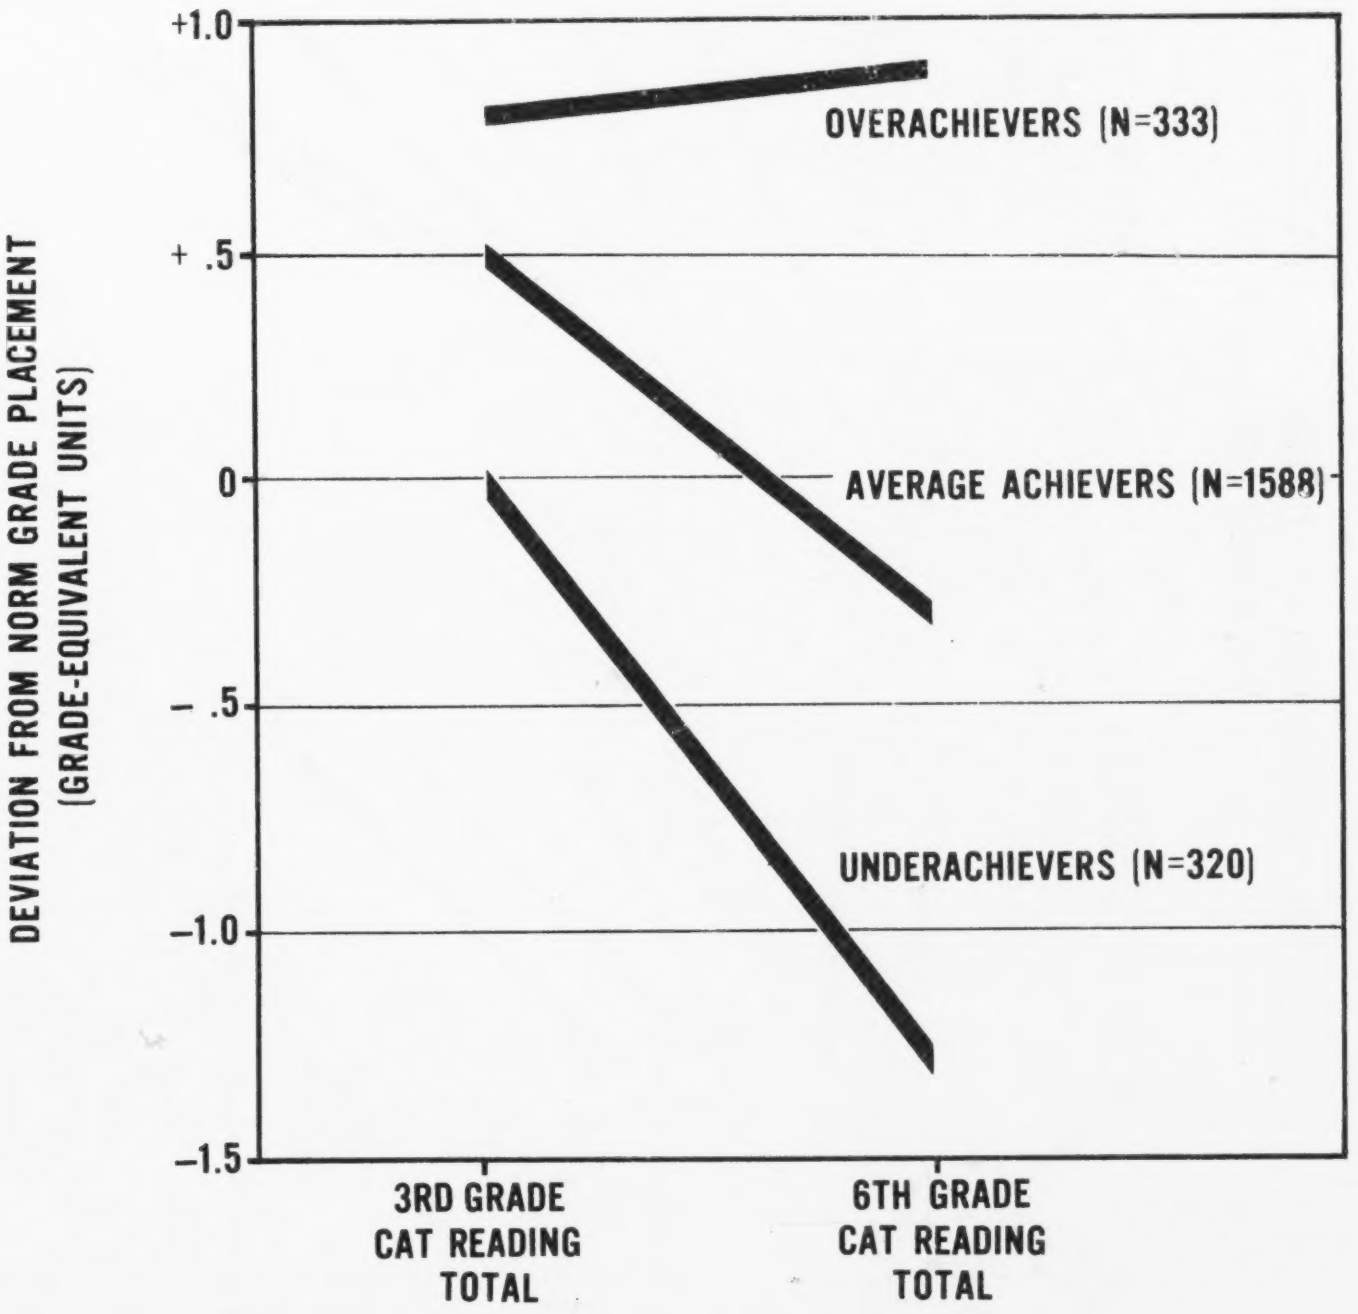

FIGURE 2

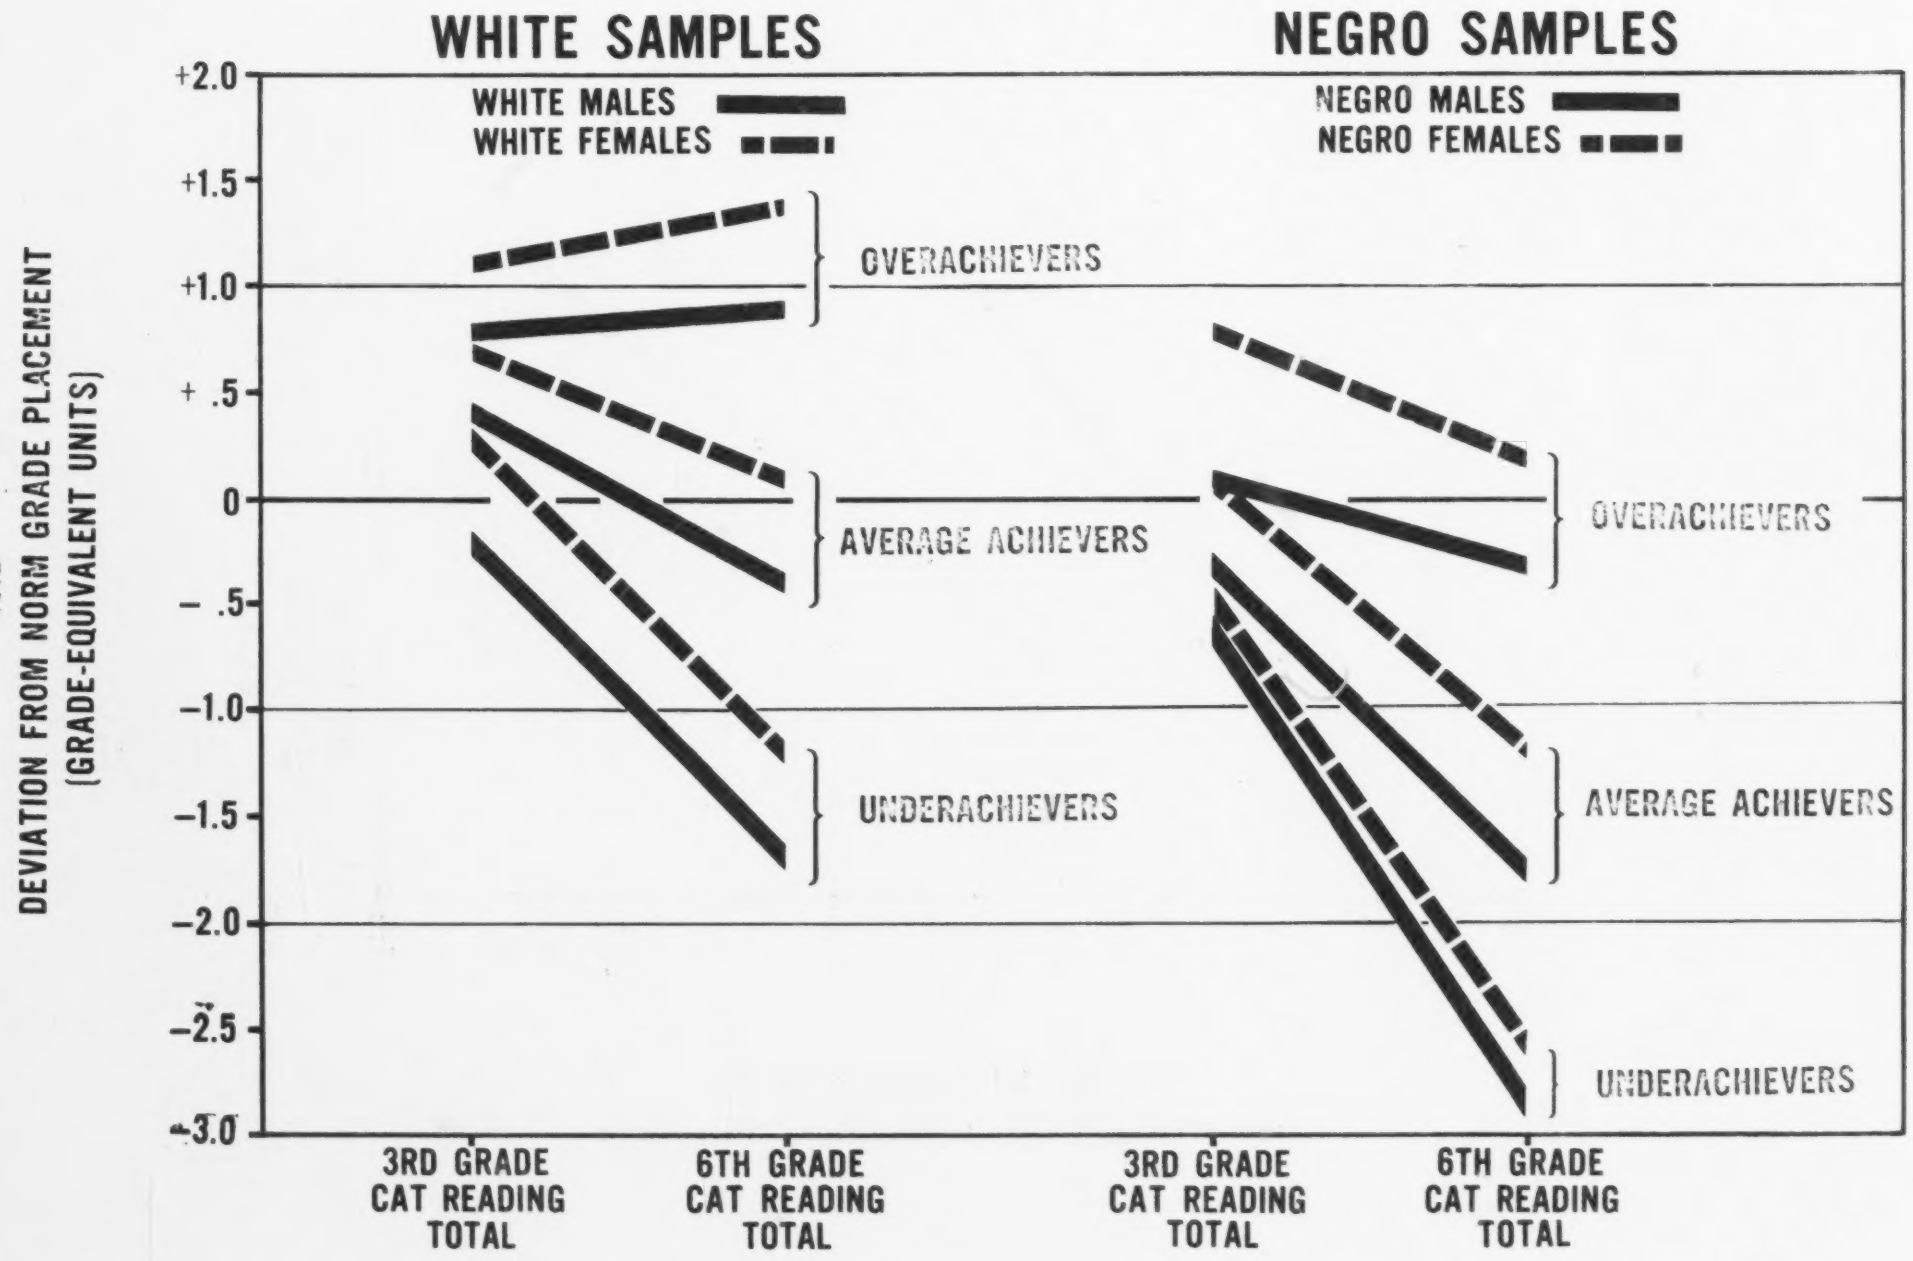
MEAN 3rd AND 6th GRADE READING LEVEL OF UNDER-, AVERAGE, AND OVERACHIEVERS CORRECTED FOR GRADE LEVEL (RACE AND SEX SAMPLES)



average achievers dropped from .5 grade equivalents above the norm in the 3rd grade to .3 grade equivalents below the norm in the 6th grade. The drop of underachievers was even greater, from a mean performance at grade placement in grade 3 to 1.3 grade equivalents below the norm in grade 6. This same pattern of change occurred in all four race-by-sex samples. Thus, whatever weaknesses in the reading curriculum, or other factors that may have resulted in the general drop relative to norm placement, the performance of over-achievers was unaffected. Further, the effect on underachievers in reading was greater than the effect on average achievers.

A test of the significance of the difference in change of the achievement groups was performed with an analysis of variance with covariate control. Results of this analysis with the white male and white female samples are given in Table 15. Differences among achievement groups in 6th grade reading level remained highly significant (1) when groups were equated on 3rd grade reading level and (2) when equated on 3rd grade reading and IQ level.

There were also some additional characteristics of note in pattern of reading achievement from grades 3 to 6 in each of the race-by-sex samples. The general fanning out of the lines that indicate change from 3rd to 6th grade (Figure 2) suggest that drop in mean performance was partly related to the initial level of reading in the 3rd grade. Negro male underachievers who had the lowest mean in the 3rd grade, relative to normative placement,

Table 15

Differences in Mean 6th Grade Reading Level of Achievement Groups Controlled for Differences in 3rd Grade Reading Level and 3rd Grade IQ Score

	Under-achievers	Average achievers	Over-achievers	F	omega^2
			WHITE MALES		
Unadjusted 6th CAT Reading	4.42	5.81	7.04	145.78[a]	21.96

Adjusted for 3rd CAT Reading	5.38	6.17	7.14	132.10[a]	21.38
Adjusted for 3rd CAT Reading and 3rd CTMM IQ	5.39	6.18	7.18	149.08[a]	24.88

Note.--Adjusted means indicate what the 6th grade reading level would have been if the groups had been equal in mean 3rd grade performance.

[a] $p < .001$

showed the greatest decrease in performance from grades 3 to 6. White female overachievers, who had the highest level of performance in the 3rd grade, showed a slight increase in mean performance in the 6th grade. The similarity in the mean change of Negro male and Negro female average achievers to that of white male and white female underachievers further supports that decrease in performance was related to initial reading level. The exceptions to this general pattern suggest that in addition to the relationship of initial standing to decrease in performance, the status of being an overachiever had a relationship to change between the two grades. Male overachievers (both races) did not decrease in reading level as much as same-race female average achievers, although these groups had similar 3rd grade reading scores. The same relationship between overachievement and change can be seen in the performance of high and low IQ groups. Low IQ overachievers did not show as great a decrease in performance as high IQ underachievers, although the latter had a higher mean 3rd grade reading score.

Discussion

Family Characteristics. Educational and occupational background of parents was found to be related to relative reading achievement; however, over-all, this relationship was quite small.

The percentage of variance accounted for across achievement groups by socio-economic measures was only 1%. Since the method that was used to calculate relative achievement could very well control out much of the variance that is common to family background and intelligence, we can conclude that the educational and occupational levels of a child's parents do have some influence on level of reading achievement that is independent of his general mental ability. This relationship of socio-economic background to reading achievement primarily reflected differences between the upper educational and occupational levels. Of the children in SES Level I (parents with college or college graduate education and executive, proprietor, and professional occupations), only 9% were underachievers. Among children in SES Level II (parents with high school or college education and administratives, small business owners, minor and semi-professional occupations), 13% were underachievers. In the lower three SES levels, percentages of underachievers were very similar, between 15% and 16%. Therefore, only in the most highly educated groups does there seem to be a significant decrease in the number of underachievers.

Data bearing on the question as to whether background has more influence on achievement of the upper or lower ability child lead to different conclusions than those reached by Curry (1962), who found that the effect of socio-economic conditions on

scholastic achievement was greater among lower mental ability groups.[9]

Our results would indicate that the effect of educational and occupational background on relative reading achievement is of similar magnitude in both high and low ability groups. In fact, the relationship was slightly stronger in the high IQ group, and particularly stronger for high IQ girls.

The most interesting findings concerned the differences in the relationship of socio-economic and other family characteristics to reading achievement when sex and mental ability were both taken into account. For girls, family background and intelligence seemed to have an additive effect on reading status. It was among bright girls that the educational background of the parents had the greatest contribution to producing average and overachievers rather than underachievers. Among high IQ boys, the relative achievement in reading did not appear to be significantly affected by parents' educational level. Among boys, on the other hand, the effect of family characteristics and intelligence on reading appeared to be a compensative relationship. It was among the low mental ability boys that parents' educational

---

[9] There are several similarities between Curry's study and the present one. In both studies the subjects were 6th graders, the California Achievement and Mental Ability Tests were used, and groups were compared across IQ and SES levels. The major difference in the studies is that Curry investigated relationships to normative level of achievement, whereas, our subjects were classified according to achievement relative to potential or expected achievement.

level had positive relationship to reading achievement. Also, having fewer siblings and an intact home, which are situations where a child is likely to receive a greater amount of attention from parents, were also related to reading status of boys in the low IQ group.

It can only be conjectured what factors lie behind the differences for boys and girls in the relationship of family background to reading achievement. A plausible hypothesis, however, is that these differences are associated with the earlier development in girls of reading skills and verbal skills in general. For girls, and particularly bright girls, reading and pre-reading activities occur prior to school age more often than for boys. At this time, parents have a greater influence on a child than when the child is in school, if only from the standpoint of the greater amount of time spent with the child. Even among bright boys, the readiness for or interest in conceptualizing the world in terms of language and reading may not come until late in the 1st or into the 2nd grade, after the school has assumed the primary role in teaching reading. Therefore, girls from homes where there is a greater interest and participation in reading activities may be in a better position than boys to profit from their parents' background in developing reading skills.

Race Differences. Differences between race were difficult to assess for two reasons. On the educational and occupational

measures, the Negro samples had a much more homogeneous distribution than the white samples, which could prevent the finding of significant differences. Second, other family characteristics, number of siblings and marital status of parents, were not strongly related to reading achievement in the white samples (the only significant differences were among low IQ level white males). In general, then, the relationships among the Negro samples were similar to those found in the white samples. There was a greater relationship of educational and occupational level to reading achievement for Negro females than for Negro males, especially for females in the high IQ group. This replicated the findings in the white samples. Family size and marital status of parents were not significantly related to reading achievement in either the Negro male or Negro female samples. There was a trend in the Negro samples suggesting that large families produce fewer underachievers than middle-size families, in contrast to the trend in the white samples. However, the number of white subjects with comparably large family size was too few to know whether this was a general relationship or one that was only characteristic of the Negro samples.

Retention (Non-promotion) in Elementary School Grades. Data on the relationship of retention in elementary school grades to relative reading achievement do not shed light on the efficacy of retaining students as means to remedy skills. The finding that overachievers were not retained significantly less than average achievers suggests

that retention may have benefitted some students.[10] The equal or slightly higher retention rate among underachievers, however, would suggest the opposite, repeating grades did not improve reading status. Perhaps the most significant implication of finding no difference in elementary school retentions for the achievement groups comes in relationship to findings reported in Part II of this report. In those analyses, retention in secondary school grades was found to be significantly higher for underachievers than for average or overachievers.[11] In view of these findings (and recognizing that retention is only one way, and not necessarily the preferred way, to correct reading deficiencies), it can be questioned whether as many course failures and retentions would have occurred for underachievers in secondary school if more of them had repeated grades in elementary school.

3rd to 6th Grade Reading Performance. It is generally felt that in the reading curriculum, basic skills should be mastered by the end of the 3rd grade, although not all children achieve this

---

[10] However, the possibility of an artifact contributing to retained students being classified as overachievers has to be considered.

[11] Studies of secondary school dropouts, using this same population (Lloyd, 1967), indicated that retention in secondary school grades was so strongly related to dropout prior to completion of high school that it could only be concluded that retention in secondary school grades led to dropout as often or more often than to remediation of deficiencies.

goal by then (Templeton, 1969). The 3rd grade also is an important point in the educational process in that research suggests that general learning patterns of children are largely determined by the end of the 3rd grade (Bloom, 1964; Vane, 1966). It therefore seemed important to determine whether the reading problems of 6th grade underachievers developed from deficiencies in primary grades or whether they stemmed from more recent difficulties encountered in elementary grades. The comparison of achievement groups on 3rd and 6th grade performance produced five findings:

(1) Underachievers had a significantly lower reading level than average or overachievers in the 3rd grade,

(2) The pattern of achievement from the 3rd to the 6th grade showed a decrease in reading relative to grade placement for underachievers and average achievers, whereas,

(3) Overachievers maintained the same superior level of performance from grades 3 to 6,

(4) The decrease in performance from grades 3 to 6 was significantly greater for underachievers than for average and overachievers,

(5) The degree to which scores changed from grades 3 to 6 was related to the level of skill (i.e., grade placement) in the 3rd grade.

The results show two factors operating to determine a pattern of reading achievement. The first is achievement status relative to ability. Being an overachiever or an underachiever, regardless of ability or intelligence level, has implications for future reading skills. The second factor is normative achievement level (i.e., in relation to standardized norms or grade placement). This achievement level in the 3rd grade is also predictive of future reading performance.

These results taken separately and as they interact together have several implications for the identification and treatment of underachievers and, hopefully, for the planning of reading curricula in general.

Finding (1) indicates that underachievement in reading begins in the primary grades for many students and that it should be possible to detect it by grade 3.[12] Both findings (1) and (4) indicate that the corrective action for underachievement in reading should be programmed as early as possible because the performance of underachievers does not remain a constant level lower than that of average achievers, but, rather, underachievers fall further behind in later grades.[13]

---

[12] Some cases of underachievement have been traced to beginnings as far back as the 1st grade (Shaw & McCuen, 1960).

[13] Analyses of the performance of these same subjects reported in Parts I and II of this study show that after grade 6, underachievers never catch up to average achievers in reading and that their performance in all subject areas in secondary school is lower than that of average achievers.

Finding (2) indicates that reading skills cannot be ignored in the elementary grades (grades 4-6). We examined our data very closely to determine whether some artifact accounted for the decrease in reading level of average achievers between these grades. This did not seem to be the case. The most likely cause for this decrease in normative placement was a de-emphasis on reading in grades 4 to 6. This de-emphasis was not necessarily in the overall reading program for the elementary grades. The results in our data could have been produced by inadequate attention to those children who had not mastered the basic skills taught in earlier grades. Finding (5) would suggest that it was the children in the low average range (those not far enough below expected level to be classified as underachievers, but not having complete mastery of basic reading skills) who were the most likely to show a decrease from grades 3 to 6.

Finding (3) suggests that overachievers have attained sufficient skills by the end of the 3rd grade to insure their continued development of reading ability even under conditions that result in a decrease in grade placement for other students. Even with overachievers, however, it is necessary to consider the relationships of both relative and normative level to the pattern of achievement from grades 3 to 6. It was true that overachievers as a total group (drawn from the full range of IQ scores) had the same high reading level in grades 3 and 6. It was also true, however, that

the majority of this group was reading above grade placement in the 3rd grade, so that adequate mastery of basic reading skills was also a general characteristic of overachievers.[14] Overachievers in the high and low IQ groups, however, did not show the same pattern of achievement. High IQ overachievers, virtually all of whom were reading above grade placement in the 3rd grade, actually accelerated in reading level from 1.3 grade units above the norm in the 3rd grade to a full two grades above placement in grade 6. In contrast, a substantial proportion of the low IQ overachievers were not reading at grade placement in the 3rd grade. The performance of this group decreased .6 grade units between the 3rd and 6th grades. Thus, normative achievement level, or mastery of basic reading skills, was related to the performance of overachievers. The decrease in performance of the low IQ overachievers, however, was only half as great as that experienced by high IQ underachievers whose 3rd grade reading level was higher, illustrating the independent relationship that relative achievement status had to the longitudinal pattern of reading achievement.

The concept of relative achievement provides useful information in that it seems to have effects that are independent of normative

---

[14] Overachievers had a mean 3rd grade reading score of 4.3, with a standard deviation of .85. The mean of the group was one standard deviation above grade placement (3.4); therefore it is estimated that 85% of that group had acquired average or better reading skills.

achievement and ability level. It would be dangerous, however, to use relative achievement without also considering normative level of achievement, i.e., to ignore a reading level below grade placement because a child is an overachiever for his mental ability level. Since both relative and normative achievement level appear to have effects on subsequent achievement, it is necessary to consider both in interpreting results of group data, particularly in translating findings into expectations for individual students.

Reading Achievement and Its Relationship to Academic Performance

Supplemental Data on High and Low IQ and SES Groups in Four Race-by-Sex Samples

This supplement contains performance data of underachievers, average achievers, and overachievers in reading within each of the four race-by-sex samples, further stratified by ability level (IQ) and by parent's socio-economic status (SES).

These data were used to supplement analyses reported in Parts II and III of this study, but were not tabled in those reports. They are summarized here so as to be available to those interested in the characteristics related to reading achievement within these more specific groupings.

The data provide the means, standard deviations, and analysis of variance comparisons across achievement groups on 57 variables measuring elementary and secondary school performance and family background characteristics.

The data are presented in 16 sections:

1. White males - High SES (levels 1-3)
2. " " - Low SES (levels 4 & 5)
3. " " - High IQ (IQ scores 100 and above)
4. " " - Low IQ (IQ scores below 100)
5. White females - High SES (levels 1-3)
6. " " - Low SES (levels 4 & 5)
7. " " - High IQ (IQ scores 100 and above)
8. " " - Low IQ (IQ scores below 100)
9. Negro males - High SES (levels 1-4)
10. " " - Low SES (level 5)
11. " " - High IQ (IQ scores 86 and above)
12. " " - Low IQ (IQ scores 85 and below)
13. Negro females - High SES (levels 1-4)
14. " " - Low SES (level 5)
15. " " - High IQ (IQ scores 86 and above)
16. " " - Low IQ (IQ scores 85 and below)

Classification of High and Low IQ groups was based on scores earned on the California Test of Mental Maturity (CTMM) administered in the 6th grade. Classification into High and Low SES levels was made using the Hollingshead Two-Factor Index of Social Position. This index consists of a weighted composite of the occupational and educational levels of the subject's father when the subject was in the 6th grade.

The stratifications into High and Low IQ and High and Low SES groups differ in the white and Negro samples. Divisions were made close to the means of the samples on these measures so as to achieve a balanced comparison. High and Low IQ levels were defined as above and below an IQ score of 100 in the white samples, and above and below an IQ score of 86 in the Negro samples. High SES consisted of levels 1 through 3 in the white samples, and 1 through 4 in the Negro samples.

In each section, the three achievement groups are compared on the same 57 variables. The variables (J) are numbered as follows:

1 Age in 6th Grade (Months)
2 Education Level of Father
3 Education Level of Mother
4 Number of Siblings
5 Occupation Level of Father
6 SES Level
7 6th Grade Point Average*
8 6th Grade CTMM IQ Score

55 ITED Vocabulary (9th Grade)
56 ITED Use of Information (9th Grade)
57 Discrepancy Score (6th CAT - Reading Total minus 6th CTMM Predicted Reading Total)

Variables followed by an asterisk (*) are fractional scores (GPA's and grade equivalent scores) that were treated as whole numbers in the computations. The decimal on means and standard deviations of these variables should be moved one place to the left for interpretation.

Coding procedures for family background and absence measures are found in the procedures sections of the main reports.

A constant of 10 was added to discrepancy scores (Variable #57) to avoid handling negative numbers in computations. The means of the race-by-sex samples (total column) therefore appear as 10 rather than 0. This score is also in grade equivalents, but treated as a whole number in computations and should have the decimal on the mean and standard deviation moved one place to the left for interpretation.

The omega^2 statistic represents the proportion of variance accounted for across achievement groups, in contrast to tables in the main reports where this statistic was given as a percentage.
